Predicting effectiveness of medication therapy management programs for congestive heart failure. To increase our understanding of the variability in medication therapy management (MTM) program outcomes for patients with congestive heart failure (CHF). Prior work has shown that approximately 18% of patients admitted to the hospital with CHF are not discharged on guidelinerecommended medications and that discharge MTM is positively associated with at least one guideline-recommended medication on discharge. An MTM program was implemented in two hospitals and an MTM agency was established with funding by foundations. Two groups of patients were identified for postdischarge MTM to include (1) patients who were discharged to MTM and (2) patients who were discharged home without MTM. A matched control group was also identified for analysis. Electronic medical records for both MTM and controls were searched to identify the type of medications they were discharged with (United Healthcare claims). Medications continued postdischarge were documented in MTM patients. Predictors of MTM and guideline-recommended discharge medications were determined using multivariable logistic regression models. One hundred ninety-three patients were discharged home with MTM and received 15,951 pharmacy prescriptions. No difference was found in discontinuing guideline-recommended discharge medications for patients discharged with MTM or home without MTM compared with controls. However, patients discharged with MTM had higher odds (odds ratio, 2.21; 95% confidence interval, 1.09-4.46) of being discharged on at least one guideline-recommended discharge medication compared with controls. The odds of being discharged on multiple guideline-recommended discharge medications were statistically significantly higher for patients discharged with MTM than controls (odds ratio, 2.47; 95% confidence interval, 1.11-5.48) and were statistically significantly greater than with home without MTM (odds ratio, 3.68; 95%
