The present invention relates to plasma display devices. More particularly, the present invention relates to a plasma display device and an image display method, in which improvements are made to the configuration of the panel structure in each of the display cells of a display panel. In recent years, the market for thin flat display panels, such as plasma display panels (PDPs), has been expanding at a rapidly increasing rate. With respect to color display systems, PDPs have attracted attention due to their high display luminance, low operating voltage, slim size, wide viewing angles, and high resolution. PDPs are required to produce a stable high-intensity discharge in each of the display cells. For this reason, it is necessary to efficiently emit secondary electrons produced by the discharge, and to prevent the dispersal of the generated charge and the occurrence of charge concentration. In the past, the configuration of the panel structure in the display cells was largely dependent on the configuration of the control electrodes (address electrode). For example, in a PDP that used scanning electrodes and sustain electrodes formed on the front surface of the substrate, the scanning electrodes were so disposed as to intersect the sustain electrodes that were adjacent in the scan direction. This type of configuration is employed in the following patent documents 1 and 2. In Patent Document 1, part of the address electrode in an area facing the scanning electrode is removed, and the remaining part of the address electrode is divided into first and second groups and is disposed on the substrate so as to be interleaved in the second direction. Each of the first and second groups

is arranged in such a manner that the first group and the second group are shifted in the second direction by a quarter-period of the addressing period. In this configuration, as shown in FIG. 29, the sustain electrodes are disposed on the address electrode so as to be parallel to the scan direction, and the discharge sustaining pulse is applied to the sustain electrodes in order to maintain the discharge at the intersections of the sustain electrodes and the address electrode. As a result, when the number of sustain electrodes, which is increased along with the number of display
