Last updated:Q: Encoding problem in Zend_Session::set I am using Zend to store some session data. Everything works fine until I try to add more than one value to the session. Here is what I am doing: // Creates and saves session object \$session = new Zend_Session_Namespace('test'); \$session->user = 'abc'; \$session->active = 1; // Attempt to update session data \$session->user = 'def'; \$session->active = 0; // Attempt to update session data \$session->user = 'ghi'; \$session->active = 0; If I output the session data, it reads: array(2) { ["user"]=> string(2) "abc" ["active"]=> int(1) } array(2) { ["user"]=> string(2) "def" ["active"]=> int(0) } array(2) { ["user"]=> string(2) "ghi" ["active"]=> int(0) } This is what I expect. The problem is, if I attempt to access the active attribute (like so: \$session->active) I get "Invalid argument type". Is there some limitation on how many sessions can be created in this way? Thanks A: The cause is that Zend_Session::set doesn't do any special handling of it's arguments. Instead, it just calls spl_object_hash() on them. Which explains why the problem only occurs when you try to add two sessions. Spl_Object_Hash expects two arguments: the identifier for the object, and the identifier of the handler (the property name to set/get). So when you add your second session object, it's not getting the handler for it's active property, so therefore you're invalid argument. I guess you could handle it by passing the handler as the third argument, but this doesn't feel like the best approach. Q: Set user login path for Meteor MongoDB backend? I have a server side app (React/Redux) and a client side app (c6a93da74d
